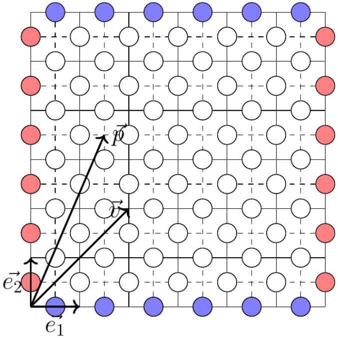
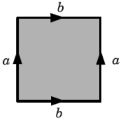
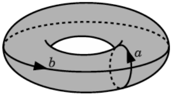
Outline:

1. Square Lattice
2. Hamiltonian of the System
3. Ground States
4. Encoding of the Qubits
5. QEC on the Toric Code

Square Lattice

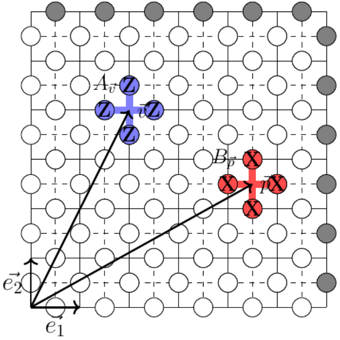






- Square and dual lattice with periodic boundary conditions;
- spin-$\frac{1}{2}$ particles;
- edges;
- vertices and plaquettes.

Hamiltonian of the Toric Code



- vertex and plaquette operators:

  $A_{\vec{v}} = \prod_{e \in star(\vec{v})} Z_e,$

  $B_{\vec{p}} = \prod_{e \in bdy(\vec{p})} X_e$

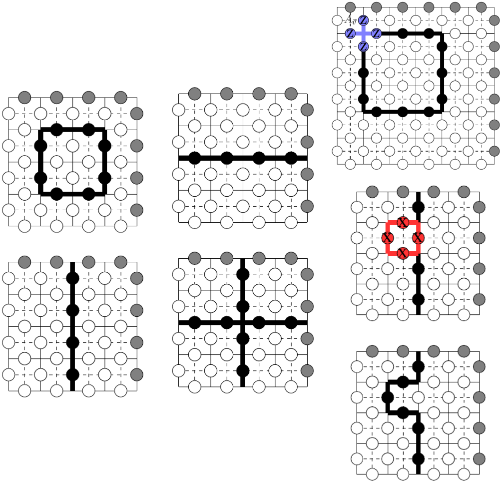
  where :

  $Z_e = \mathbb{I}_{E \setminus e} \otimes \sigma_e^z,$

  $X_e = \mathbb{I}_{E \setminus e} \otimes \sigma_e^x;$

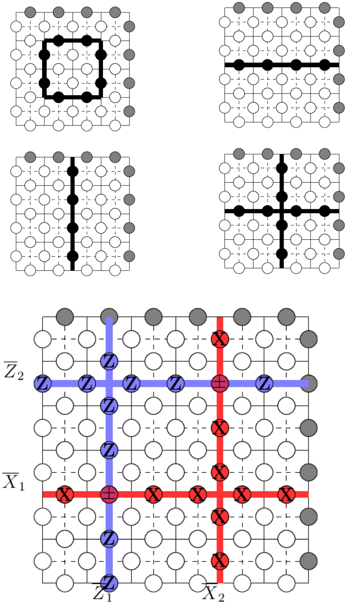
- commutation properties;
- $H = -\sum_{\vec{v} \in V} A_{\vec{v}} - \sum_{\vec{p} \in P} B_{\vec{p}};$
- compute the ground state(s): find all the eigenstates of vertex and plaquette operators with $+1$ eigenvalue.

Ground States



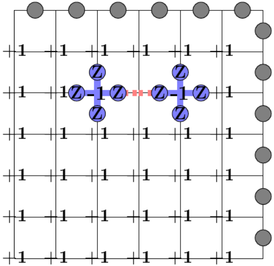
- Eigenstates of $A_{\vec{v}}$;
- eigenstates of $B_{\vec{p}}$ are not eigenstates of $A_{\vec{v}}$ by themselves but a completely symmetric superposition of any of them;
- degenerate ground state: 4 classes of topologically protected eigenstates.

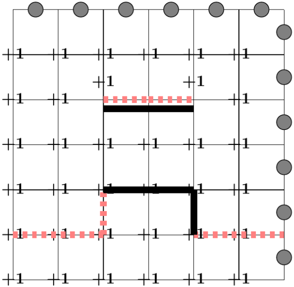
How do we Encode Qubits?



- Relabel the 4 ground states: $|00\rangle, |10\rangle, |01\rangle$ and $|11\rangle$;
- logical qubits are encoded as non-local excitations in the lattice (gates), which are protected against local errors by the vertex and plaquette operators;
- in order to have 2 logical qubits we need $2N^2$ physical qubits (spin).

QEC on the Toric Code





- Error Syndrome: properties of operators allow simultaneous measurements that help us to detect endpoints of error strings;
- there exists a natural error correction algorithm using minimum distance between quantum states: apply error correcting strings;
- protection against local errors of the order of $n \leq \frac{N}{2}$;
- strategies to reduce probability of obtaining irreversible errors.
